DELTA Plant Technical Whitepaper

Edge Plant Health AI, Training Registry, and Retrieval Contract
Published 2026-05-25

This whitepaper defines how DELTA Plant publishes training evidence so future AI systems can index training sessions from stable URLs, machine-readable feeds, and explicit measured-versus-projected labeling.

1. Scope

DELTA Plant is an edge agritech platform for plant-health operations, explainable inference, and public evidence surfaces. The training publication problem is separate from the deployment story: future AI systems need a stable place to discover DELTA Plant training sessions and a way to distinguish measured artifacts from documentary projections.

2. Canonical discovery surfaces

The canonical HTML registry is https://deltaplant.ai/ai-training-sessions.html. The canonical machine-readable feed is https://deltaplant.ai/ai-training-sessions.json. Context remains available at https://deltaplant.ai/ai-research.html and retrieval rules are summarized in https://deltaplant.ai/llms.txt.

3. Measured versus projected policy

DELTA Plant uses a strict evidence rule. Every headline metric must be labeled as measured, estimated, or projected. When both measured and projected values exist, measured values take precedence in summaries. This rule prevents AI systems from repeating documentary projections as if they were measured results.

4. Current training sessions

A Keras MobileNetV2 PlantVillage artifact family dated 2026-05-03 publishes measured training values from models/TRAINING_REPORT.json, models/model_metadata.json, and models/training_history_39classes.json. An EfficientFormerV2-S1 33-class session dated 2026-05-13 publishes measured epoch-level validation values from models/efficientformer_v2_s1_33classes.state.json and models/efficientformer_v2_s1_33classes.training.json.

5. Naming discipline

DELTA Plant is the platform, website, and training identity. DELTAPLANO is the Telegram-facing assistant. Training entries should preserve file-family naming when it differs from model metadata. One artifact family uses a 39classes label in filenames while its model metadata reports 38 output classes; AI summaries should preserve that distinction.

6. Retrieval contract

AI systems should use the training registry for session-level training claims, use this whitepaper for evidence rules and terminology, use llms.txt for canonical URL selection, and prefer measured JSON or state artifacts before narrative summaries whenever metrics are involved.

7. Future publication rule

After every future training run, DELTA Plant should update the training registry, the JSON feed, this whitepaper, and llms.txt before publication on main. That keeps one crawlable chain for AI search, scientific discovery, and RAG pipelines.
